5.1 Contour-based techniques for image segmentation

Image segmentation is the process of **assigning a label to every pixel in an image** such that pixels with the same label share certain characteristics. The techniques addressing those problems can be classified into to major groups:

- Those producing regions with similar properties (*e.g.*, intensity, color, texture, or location in the image), addressed by classical segmentation methods and some DNN models (like SAM).
- Those segmenting regions with **similar meaning** (*e.g.*, **semantic segmentation** where pixels belonging to the same object category are assigned to the same region, or **instance segmentation** where each region represents an object, see Fig.1). This is faced by Deep NN methods.

Fig. 1: Example of instance segmentation where each region corresponds to an object in the scene.

Classical methods can be further classifed into:

- **Contour-based techniques**, which attempt to identify the image regions by detecting their contours. Edge pixels enclose a region with similar intensities.
- **Clustering-based techniques** that group together pixels that are share some properties.

In this book we are going to experience both, starting with **contour-based techniques**, whose are based on detecting specific contours in the image (e.g. circles). In this context, image contours are defined as edge pixels that enclose a region.

Contour-based techniques could be roughly classified into:

- **Local tecniques.** Try to segment regions by detecting closed contours, which typically enclose pixels with similar intensities.
  - LoG + zero crossing.
  - Edge following (Canny operator).
- **Global techniques.** Detect particular shapes in the image (circles, lines, etc.).
  - Hough transform.

This notebook will cover the **Hough transform** (section 5.1.1), a contour-based technique that can be used for detecting regions with an arbitrary shape in images.

Problem context - Self-driving car

A prestigious company located at PTA (The Andalusia Technology Park) is organizing a hackathon for this year in order to motivate college students to make further progress in the autonomous cars field. Computer vision students at UMA decided to take part in it, but the organizers have posed an initial basic task to guarantee that participants have expertise in image processing techniques.

This way, the company sent to students a task for **implementing a basic detector of road lane lines using OpenCV in python**. We are lucky! These are two tools that we know well ;).

Detecting lines in a lane is a fundamental task for autonomous vehicles while driving on the road. It is the building block to other path planning and control actions like breaking and steering.

So here we are! We are going to detect road lane lines using Hough transform in OpenCV.

```
In [1]:  import numpy as np
         import cv2
         import math
         import matplotlib.pyplot as plt
         import matplotlib
         import scipy.stats as stats

         matplotlib.rcParams['figure.figsize'] = (10.0, 10.0)
         images_path = './images/'
```

5.1.1 Hough transform

The **Hough Transform** is a technique for the detection of arbitrary shapes in an image. For that, such shapes must be expressed in:

- analytical form (**classic Hough**), e.g. using the mathematical representation of lines, circles, ellipses, etc., or
- in a numerical form (**generalized Hough**) where the shape is given by a table.

Since our goal is to detect lines, we will focus here on analytically expressed shapes. Specifically, a line can be represented analytically as:

$$y = ax + b$$

where a is the slope and b is the y-incertcept, what is called the **explicit representation** of a line. However, this representation is problematic when representing vertical lines ($m = \inf$) or when discretizing the possible values for m, as we will see). Other option is its **parametric form**:

$$\rho = x \cos \theta + y \sin \theta$$

where ρ is the perpendicular distance from the origin $(0,0)$ to the line, and θ is the angle formed by this perpendicular line and the horizontal axis measured in counter-clockwise (see Fig. 3). Thereby, we are going to represent lines using the pair of parameters (ρ, θ).

Fig. 3. Parametric representation of a line.

The Hough transform works by a voting procedure, which is carried out in a parameter space (ρ, θ in our case). This technique consists of the following steps:

1. **Build an accumulator matrix**, where rows index the possible values of ρ, and columns those for θ. For example, if the possible values for ρ are $0, 1, 2, \ldots d$ (where d is the max distance e.g. diagonal size of the image) and those for θ are $0, 1, 2 \ldots 179$, the matrix shape would be $(d, 180)$.

```
In [2]:   # Define possible rho and theta values
          theta_values = [0,np.pi/4,np.pi/2,3*np.pi/4]
          rho_values = [0,1,2,3,4,5]

          # Create the accumulator
          acc = np.zeros([len(rho_values),len(theta_values)])
```

2. **Binarize the input image** to obtain pixels that are candidates to belong to the shape contours (e.g. by applying an edge detector).

In [3]:
```python
# Coordinates of white points in binary image
xs = np.array([1,2,3])
ys = np.array([4,3,2])

# Initial image
plt.subplot(221)
blank_image = np.zeros((6,4,1), np.uint8)
blank_image[ys,xs] = 255
plt.imshow(blank_image, cmap='gray');
plt.title('Initial binary image')

# Show them!
plt.subplot(222)
plt.plot(xs,ys,'rx')
plt.axis('scaled')
axes = plt.gca()
axes.set_xlim([0,4])
axes.set_ylim([0,6])
plt.gca().invert_yaxis()
plt.title('White pixels in binary image');
```

3. For each candidate (white pixel):
   A. **Evaluate**: Since the point coordinates (x, y) are known, place them in the line parametric form and iterate over the possible values of θ to obtain the values for ρ. In the previous example $\rho_i = x \cos \theta_i + y \sin \theta_i, \forall i \in [0, 180]$
   B. **Vote**: For every obtained pair (ρ_i, θ_i) increment by one the value of its associated cell in the accumulator.

If we do this with an accumulator with an enough resolution, we would get a sinusoid.

In [4]:
```python
# For each white pixel

for i in range (0,len(xs)):
    x = xs[i]
    y = ys[i]

    # Show the point voting
    subplot_index = str(32) + str(i*2+1)
    plt.subplot(int(subplot_index))
    plt.axis('scaled')
    axes = plt.gca()
    axes.set_xlim([0,4])
    axes.set_ylim([0,6])

    plt.plot(xs,ys,'rx')
    plt.plot(x,y,'co')

    plt.title('Pixel being evaluated at iteration ' + str(i+1))
    plt.gca().invert_yaxis()

    # Ecaluate the (x,y) coordinates for different values of theta, and
    # retrieve rho
    for theta_index in range(0,len(theta_values)):
        theta = theta_values[theta_index]
        rho = x*np.cos(theta) + y*np.sin(theta)
        rho = int(np.round(rho))
        # Vote!
        acc[rho][theta_index] += 1.0

    # Show the acccumulator
    subplot_index = str(32) + str(i*2+2)
    plt.subplot(int(subplot_index))
    plt.imshow(acc,cmap='gray',vmax=3);
    plt.xticks([0, 1, 2, 3], ['0','pi/4','pi/2','3pi/4'])

    plt.title('Accumulator values')
```
Pixel being evaluated at iteration 1
## Accumulator values

Pixel being evaluated at iteration 2
Accumulator values

Pixel being evaluated at iteration 3
## Accumulator values

4. Finally, **obtain the shape candidates** by setting a threshold to control how many votes needs a pair (ρ, θ) to be considered a line, and by applying local maxima in the accumulator space.
Fig. 3. Left, image space. Right, parameter space illustrating the evolution of the votes. Note that in this example θ have only 8 possible values.

The idea behind this algorithm is that when a pixel in the image space votes for all the lines that go through it in the parameter space, when a second pixel belonging to the same line votes, then the line connecting both pixels would have two votes.

OpenCV pill

OpenCV implements the method `cv2.HoughLines()` for detecting lines using the Hough transform. However, prior to its usage, and as commented in the `step 1.` of the algorithm, it is needed a binary image. For that we are going to resort to our old friend the Canny algorithm, so the detected edges will be the white pixes in the binary image.

As we now, noisy images seriously hamper the performance of computer vision techniques, and since cv2.Canny() does not include blurring, we provide here a method called `gaussian_smoothing()` to assist you in that task.

```python
def gaussian_smoothing(image, sigma, w_kernel):
    """ Blur and normalize input image.

        Args:
            image: Input image to be binarized
            sigma: Standard deviation of the Gaussian distribution
            w_kernel: Kernel aperture size

        Returns:
            binarized: Blurred image
    """

    # Define 1D kernel
    s=sigma
    w=w_kernel
    kernel_1D = [np.exp(-z*z/(2*s*s))/np.sqrt(2*np.pi*s*s) for z in range(-w,w+1

    # Apply distributive property of convolution
    kernel_2D = np.outer(kernel_1D,kernel_1D)

    # Blur image
    smoothed_img = cv2.filter2D(image,cv2.CV_8U,kernel_2D)

    # Normalize to [0 254] values
    smoothed_norm = np.array(image.shape)
```

```python
        smoothed_norm = cv2.normalize(smoothed_img,None, 0, 255, cv2.NORM_MINMAX)

        return smoothed_norm
```

ASSIGNMENT 1: Detecting lines with Hough

Your first task is to apply `cv2.HoughLines()` to the image `car.png`, a test image taken from the frontal camera of a car. Draw the resultant lines using `cv2.line()`.

The main inputs of `cv2.HoughLines()` are:

- *image*: binary input image
- *rho*: distance resolution of the accumulator in pixels (usually 1, it may be bigger for high resolution images)
- *theta*: angle resolution of the accumulator in radians. (usually $\frac{\pi}{180}$)

- *threshold*: only line candidates having a number of votes $>$ threshold are returned.

And it returns:

- a $(n\_lines x 1 x 2)$ array containing, in each row, the parameters of each detected line in the $[\rho, \theta]$ format.

Note that, for drawing the lines, you have to transform the resultant lines from the (ρ, θ) space to Cartesian coordinates.

Try different parameter values until you get something like this:

Fig. 4. Example of lines detection.

```python
In [6]:  # Assignment 1
         # Read the image
         image = cv2.imread(images_path + "car.png",-1)

         # Convert to RGB and get gray image
         image = cv2.cvtColor(image, cv2.COLOR_BGR2RGB) #la imagen original esta en BGR,
         gray = cv2.cvtColor(image, cv2.COLOR_RGB2GRAY)

         # Blur the gray image
```

```python
gray = gaussian_smoothing(gray,2,5)

# Apply Canny algorithm
edges = cv2.Canny(gray,100,200,apertureSize = 3)

# Search for lines using Hough transform
lines = cv2.HoughLines(edges, rho=1, theta=np.pi/180, threshold=170) # con un th
#detecta muchas más lineas además de la de la carretera

# For each line
for i in range(0, len(lines)):

    # Transform from polar coordinates to cartesian coordinates
    rho = lines[i][0][0] # accede a la poscion i, la posicion i puede tener vari
    #[rho, theta] por eso es lines [i][0], para acceder a rho debemos acceder al
    theta = lines[i][0][1]

    a = math.cos(theta)
    b = math.sin(theta)

    x0 = a * rho # x0 cordenada x y y0 coordenada y, de un punto de la línea i,
    y0 = b * rho

    # Get two points in that line
    x1 = int(x0 + 2000*(-b));
    y1 = int(y0 + 2000*(a))
    pt1 = (x1,y1)
    x2 = int(x0 - 2000*(-b))
    y2 = int(y0 - 2000*(a))
    pt2 = (x2,y2)

    # Draw the line in the RGB image
    cv2.line(image, pt1, pt2, (255,0,0), 3, cv2.LINE_AA)

# Show resultant image
plt.imshow(image);
```

5.1.2.1 Probabilistic Hough transform

For high-resolution images and large accumulator sizes the Hough transform may need long execution times. However, in applications like autonomous cars a fast execution is mandatory. For example, having a car moving at 100km/h covers ~ 28 meters in a second. Imagine how much lines can change in that time!

OpenCV pill

OpenCV provides with the method `cv2.HoughLinesP()` a more complex implementation of the Hough Line Transform, which is called **probabilistic Hough Transform**. This alternative does not take all the points in the binary image into account, but a random subset of them that are still enough for line detection. This also results in lower thresholds when deciding if a line exists or not.

ASSIGNMENT 2: Another option for detecting lines

Apply `cv2.HoughLinesP()` to the image `car.png` and draw the detected lines.

This function returns:

- line segments `[x1,y1,x2,y2]` instead of the line equation parameters.

For that, two additional arguments are needed:

- minLineLength: line segments shorter than that are rejected.
- maxLineGap: maximum allowed gap between points on the same line to link them.

Try different parameter values until you get something like this:

Fig. 5. Lines detection example with the probabilistic Hough Transform.

```
In [7]:   # Assigment 2
          # Read the image
          image = cv2.imread(images_path + "car.png",-1)

          # Convert to RGB and get gray image
          image = cv2.cvtColor(image, cv2.COLOR_BGR2RGB)
          gray = cv2.cvtColor(image, cv2.COLOR_RGB2GRAY)
```

```python
# Blur the gray image
gray = gaussian_smoothing(gray,1,2)

# Apply Canny algorithm
edges = cv2.Canny(gray,100,200,apertureSize = 3)

# Search for lines using probabilistic Hough transform
rho = 1
theta = np.pi/180
threshold = 200
lines = cv2.HoughLinesP(edges, rho, theta, threshold,
                        minLineLength=60,maxLineGap=10)
# For each line
for line in lines:

    # Draw the line in the RGB image
    x1,y1,x2,y2 = line[0] #Accdemos al primer y unico elemento del array line
    cv2.line(image,(x1,y1),(x2,y2),(255,0,0),2)

# Show resultant image
plt.imshow(image);
```

Thinking about it (1)

Now that you have played with the Hough Transform, **answer the following questions**:

- In the first assignment, we obtained an image with a number of red lines drawn on it. However, these lines goes over pixels in the image that do not contains lines! (*e.g.* belonging to the sky). What could we do to fix this, that is, obtain the pixels belonging to lines in the image?

  Yo creo, que una solución adecuada es la que utiliza el método HoughLinesP. Este consiste en agrupar segmentos de líneas con puntos unidos, en vez de lineas contínuas enteras. Estos segmentos, son introducidos en la imagen final si superan el minLineLength. Dos segmentos alineados, se unen como una única línea si la separación entre ambos es inferior a maxLineGap. De esta forma, conseguimos que

en vez quedar lineas continuas por todo el dibujo, encontramos muchos segmentos que forman líneas entre ellos.

- Without restrictions regarding execution time, which method would you use, Hough Transform or its probabilistic counterpart?

  Creo que me inclinaría por el clásico. Es mucho más exhaustivo, el hecho de que coja puntos de forma aleatoria, no es muy riguroso que digamos. Tendría que realizarle retoques para que las líneas no fueran contínuas por toda la imagen, pero creo que los resultados serían mucho mejores.

- Could there be a cell in the accumulator with a value higher than the number of white pixels in the binary image? why?

  No, cada pixel vota por una línea en cada una de las direcciones que vayamos a usar. Por tanto, en el mejor de los casos,(todos los píxeles blancos de la imagen binarizada votan por una misma línea) una línea no puede tener más de un voto por cada píxel.

- Which should be the maximum value for ρ in the accumulator? Why?

  Pues el máximo, en el mejor caso, en el que todos los píxeles votan por una misma línea, sería el numero de píxeles blancos de la imagen binarizada.

OPTIONAL

Think about any other application where the finding of straight lines could be useful. Get some images related to said application and detect lines with the Hough transform!

Podríamos usarlo para detectar el camino que puede o no seguir un robot de limpieza que se mueve por una habitación. Para este ejemplo voy a fotografiar mi habitación y probar esta tecnica de detección de imagenes. Para ello, voy a añadir a la entrega mi carpeta images. Vamos a hacer un primer intento con HughP, en el que ajustaremos como buenamente podamos los parámetros.

```python
In [8]:
# Read the image
image = cv2.imread(images_path + "miCuarto.png",-1)

# Convert to RGB and get gray image
image = cv2.cvtColor(image, cv2.COLOR_BGR2RGB)
gray = cv2.cvtColor(image, cv2.COLOR_RGB2GRAY)

# Blur the gray image
gray = gaussian_smoothing(gray,1,2)

# Apply Canny algorithm
edges = cv2.Canny(gray,100,200,apertureSize = 3)

# Search for lines using probabilistic Hough transform
rho = 1
theta = np.pi/180
threshold = 10
lines = cv2.HoughLinesP(edges, rho, theta, threshold,
                        minLineLength=20,maxLineGap=30)
# For each line
for line in lines:
```
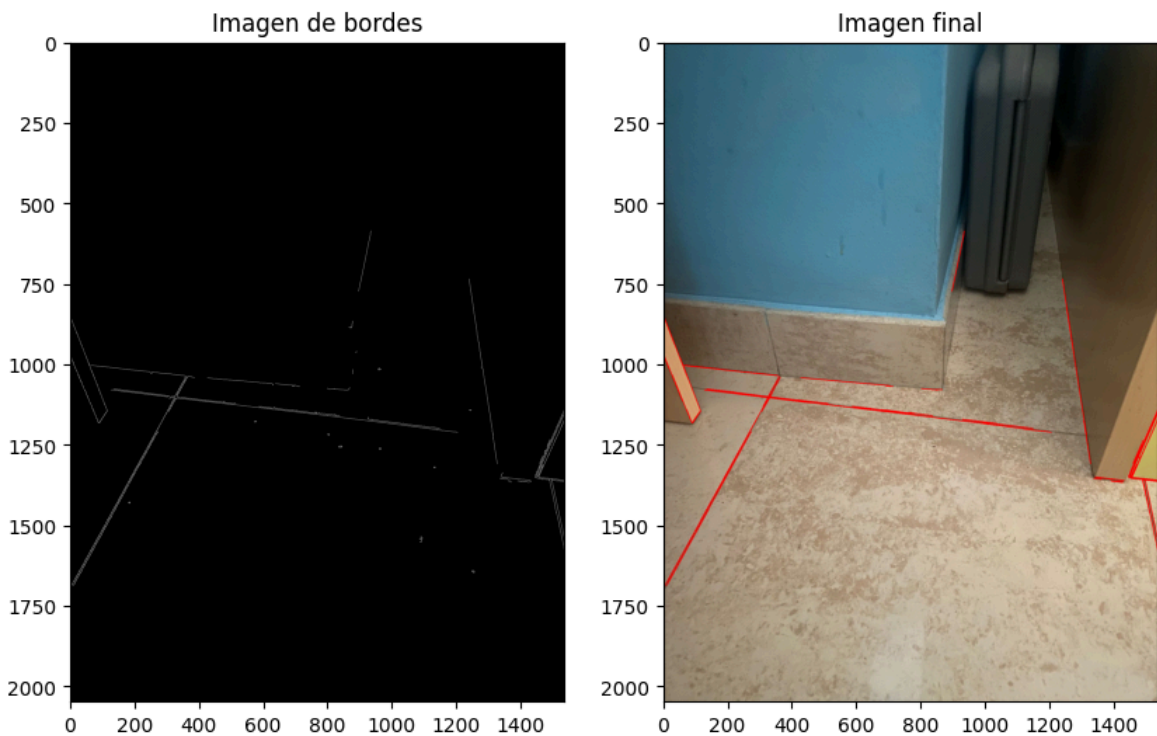

```
    # Draw the line in the RGB image
    x1,y1,x2,y2 = line[0] #Accdemos al primer y unico elemento del array line
    cv2.line(image,(x1,y1),(x2,y2),(255,0,0),2)

# Show resultant image
# Display first one
plt.subplot(121)
plt.imshow(edges, cmap='gray')
plt.title('Imagen de bordes')

# Display second one
plt.subplot(122)
plt.imshow(image, cmap='gray')
plt.title('Imagen final')
```

Out[8]:   Text(0.5, 1.0, 'Imagen final')

Ahora vamos a probar con Hough normal.

In [9]:
```
# Read the image
miCuarto = cv2.imread(images_path + "miCuarto.png",-1)

# Convert to RGB and get gray image
miCuarto = cv2.cvtColor(miCuarto, cv2.COLOR_BGR2RGB) #la imagen original esta en
grayCuarto = cv2.cvtColor(miCuarto, cv2.COLOR_RGB2GRAY)

# Blur the gray image
grayCuarto = gaussian_smoothing(grayCuarto,2,5)

# Apply Canny algorithm
bordes = cv2.Canny(grayCuarto,100,200,apertureSize = 3)

# Search for lines using Hough transform
lineas = cv2.HoughLines(bordes, rho=1, theta=np.pi/180, threshold=80) # con un t
#detecta muchas más lineas además de la de la carretera
```

```python
# For each line
for i in range(0, len(lineas)):

    # Transform from polar coordinates to cartesian coordinates
    rho = lineas[i][0][0] # accede a la poscion i, la posicion i puede tener var
    #[rho, theta] por eso es lines [i][0], para acceder a rho debemos acceder al
    theta = lineas[i][0][1]

    a = math.cos(theta)
    b = math.sin(theta)

    x0 = a * rho # x0 cordenada x y y0 coordenada y, de un punto de la línea i,
    y0 = b * rho

    # Get two points in that line
    x1 = int(x0 + 2000*(-b));
    y1 = int(y0 + 2000*(a))
    pt1 = (x1,y1)
    x2 = int(x0 - 2000*(-b))
    y2 = int(y0 - 2000*(a))
    pt2 = (x2,y2)

    # Draw the line in the RGB image
    cv2.line(miCuarto, pt1, pt2, (255,0,0), 3, cv2.LINE_AA)

# Show resultant image
# Display first one
plt.subplot(121)
plt.imshow(edges, cmap='gray')
plt.title('Imagen de bordes')

# Display second one
plt.subplot(122)
plt.imshow(miCuarto, cmap='gray')
plt.title('Imagen final')
```
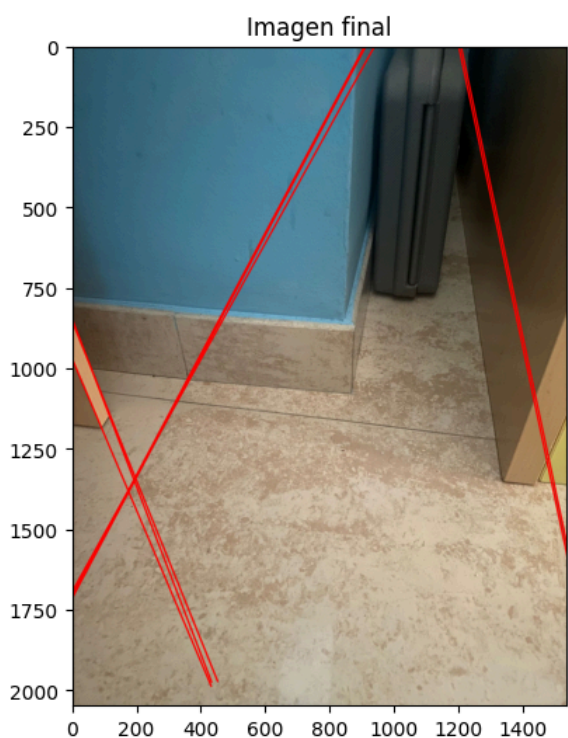

Out[9]: Text(0.5, 1.0, 'Imagen final')

Conclusión

- *Los resultados con HoughLinesP, son mucho mejores, parece ser que me equivoqué en el segundo thinking about it, pensando que los resultados del clásico serían mejores. No obstante supongo que también dependerá de la imágen que usemos. El problema de mi cuarto esque tiene líneas en el suelo y estas se detectan mejor que las líneas de la pared, lo cual no habia pensado que pasaría.*

END OF OPTIONAL PART

Conclusion

Terrific work! In the road lane lines detection context you have learned:

- to detect shapes in images using Hough transform .

Also, you obtained some knowledge about:

- self-driving cars and computer vision, and
- lane line detection for autonomous cars.

See you in the next one! Keep learning!
